Abstract

In this study, we used a bioinformatic approach to identify genes whose expression is dysregulated in human prostate cancers. One of the most dramatically downregulated genes identified encodes CYP27A1, an enzyme involved in regulating cellular cholesterol homeostasis. Importantly, lower CYP27A1 transcript levels were associated with shorter disease-free survival and higher tumor grade. Loss of CYP27A1 in prostate cancer was confirmed at the protein level by immunostaining for CYP27A1 in annotated tissue microarrays. Restoration of CYP27A1 expression in cells where its gene was silenced attenuated their growth *in vitro* and

tumor xenografts. Studies performed *in vitro* revealed that treatment of prostate cancer cells with 27-hydroxycholesterol (27HC), an enzymatic product of CYP27A1, reduced cellular cholesterol content in prostate cancer cell lines by inhibiting the activation of sterol regulatory-element binding protein 2 and downregulating low-density lipoprotein receptor expression. Our findings suggest that CYP27A1 is a critical cellular cholesterol sensor in prostate cells and that dysregulation of the CYP27A1/27HC axis contributes significantly to prostate cancer pathogenesis. *Cancer Res*; 1–12. ©2017 AACR.

Introduction

Prostate cancer is the most common non-skin cancer among men and the second leading cause of cancer death (1). Although the underlying causes of prostate cancer remain unclear, multiple epidemiologic studies have suggested that hypercholesterolemia is associated with an increased risk of high-grade metastatic disease (2–6). Indeed, prostate cancer cells and those of other solid tumors have been shown to contain higher cholesterol levels than juxtaposed normal cells (7, 8). Thus, it is possible that increased cholesterol content affects prostate cancer growth by

satisfying the need of proliferating cells for a key component of cell membranes. Another contemporary opinion is that increased cellular cholesterol within mitochondrial membranes renders cells resistant to many chemotherapeutics (9). It has also been suggested that cholesterol affects prostate cancer growth by serving as a precursor for the production of intratumoral androgens (10). It is not surprising, therefore, that inhibitors of HMG-CoA-reductase (HMGCR; statins), drugs that block cholesterol synthesis and reduce serum cholesterol and inhibit prostate cancer cell growth *in vitro* (11, 12), are associated with reduced prostate cancer progression following treatment with surgical prostatectomy (13) or brachytherapy (14) and have been shown in population studies to be associated with a lower risk of developing metastatic or fatal prostate cancer (15–18). Given these positive data, it is noteworthy that not all studies have linked hypercholesterolemia with higher prostate cancer risk (19). Likewise, the data on statins are not universally positive in terms of their association with prostate cancer risk and/or prostate cancer progression with several studies finding no such association or with increased risk (20–23). Importantly, hypercholesterolemia and statin use influence serum cholesterol levels. Whether these changes effect intratumoral cholesterol is not clear. As such, given the scientific plausibility that cholesterol promotes prostate cancer progression, albeit in the face of equivocal epidemiologic data, it is important to understand the molecular mechanisms used by prostate cancer cells to regulate intracellular cholesterol.

In humans, the regulation of cellular cholesterol homeostasis is achieved primarily through the coordinated activity of two classes of transcription factors: Sterol regulatory element-binding proteins (SREBP) and Liver X Receptors (LXR; refs. 24–26). LXRs can regulate cholesterol efflux by inducing the expression of mRNAs encoding the reverse cholesterol ATP-binding cassette (ABC) transporters ABCA1 and ABCG1 (27), whereas SREBPs promote endogenous cholesterol synthesis and uptake of extracellular

79	cholesterol by inducing the expression of genes such as HMGCR	138
80	and the low-density lipoprotein receptor (LDLR). Targeting these	139
81	pathways has been shown to be an effective strategy to inhibit	140
82	growth in relevant cellular and animal models of prostate cancer	141
83	(28, 29).	142
84	Considering what is known about the pathobiology of cholest-	143
85	terol in prostate cancer, it is clear that these cancer cells have	
86	evolved mechanisms to bypass the tight homeostatic regulation of	144
87	intracellular cholesterol, and this represents a potential vulnera-	145
88	bility for intervention. With this idea in mind, we sought to	146
89	identify genes involved in cholesterol homeostasis whose expres-	147
90	sion was dysregulated in prostate cancer. We reasoned that such	148
91	an approach would also yield novel targets, which could be	149
92	pharmaceutically exploited to have useful clinical activity. To	150
93	achieve this goal, a list of genes with known involvement in	151
94	cholesterol homeostasis was assembled with each gene being	152
95	ranked according to the strength of the correlation between its	
96	expression level and prostate cancer clinical outcomes using	153
97	publicly available data. Using this approach, it was determined	154
98	that the expression of CYP27A1, a gene that encodes sterol 27-	155
99	hydroxylase, a cytochrome P450 oxidase that converts cholesterol	156
100	into 27-hydroxycholesterol (27HC), was dramatically downreg-	157
101	ulated in prostate cancer when compared with benign prostate	158
102	tissue (30). Although most cholesterol is catabolized by CYP7A1	159
103	in the liver, CYP27A1 is the rate-limiting step in the alternate or	160
104	"acidic pathway" of bile acid synthesis. Further, it has been shown	
105	that 27HC, secondary to its interaction with INSIG-2 in the	161
106	endoplasmic reticulum, inhibits the processing events required	162
107	for the activation of SREBP2 (31). In this manner, 27HC serves as a	163
108	component of a negative feedback loop that regulates cholesterol	164
109	biosynthesis. Further, 27HC, functioning as an LXR agonist, can	165
110	also enhance cholesterol efflux by upregulating the transcription	166
111	of cholesterol transporters to further limit cellular cholesterol	167
112	accumulation. However, the significance of this regulatory loop in	168
113	prostate cancer pathogenesis has not been established. In this	169
114	study, a combination of bioinformatics, genetics, and pharmaco-	170
115	logy has been used to determine the importance of CYP27A1	171
116	and 27HC in cholesterol homeostasis in prostate cancer. Further,	172
117	it is shown that dysregulation of CYP27A1 expression and its	
118	metabolite (27HC) can affect the pathobiology of prostate cancer.	
119	Together, these studies also highlight the potential clinical utility	
120	of restoring cholesterol homeostasis in prostate cancer as a means	
121	to treat or prevent this disease.	
122	Materials and Methods	
123	Bioinformatic analysis	
124	<i>Association of CYP27A1 expression with prostate cancer clinical</i>	
125	<i>features.</i> Using logistic regression in R, expressions of genes	
126	involved in cholesterol regulation (derived from gene ontology	
127	analysis) extracted from The Cancer Genome Atlas (TCGA) were	
128	assessed for their ability to predict Gleason score (6, 7, 8, >9),	
129	pathologic T-Stage (t2a, t2b, t2c, t3a, t3b, t4), and pathologic N-	
130	Stage (n0, n1) with each clinical feature modeled as an ordered	
131	factor. ORs, confidence intervals (CI), and two-tailed <i>P</i> values	
132	were calculated using R.	
133	<i>CYP27A1 mRNA levels and Gleason score.</i> These results are based	
134	upon data generated by the TCGA Research Network: http://	
135	cancergenome.nih.gov/ . Normalized gene expression data and	
136	clinical information for TCGA-Prostate Adenocarcinoma (PRAD)	
	were downloaded from The Broad Institute TCGA GDAC Firehose	138
	at http://gdac.broadinstitute.org . At the time of data access, 269	139
	primary tumor samples were annotated for both gene expression	140
	and clinical data. Gleason score data were then categorized into	141
	three groups (Gleason score <7, =7, or >7). <i>P</i> values were	142
	determined using a one-way ANOVA.	143
	<i>PSA-free survival analysis for CYP27A1 mRNA.</i> The raw data for	144
	GSE21032 were downloaded from GEO, normalized with Robust	145
	Multi-array Average approach, and summarized at the transcript	146
	level using the oligo package in R. Biochemical recurrence in this	147
	dataset was defined as PSA \geq 0.2 ng/mL on two occasions. The	148
	Kaplan–Meier plot of PSA-free survival was generated in R with	149
	patients categorized into low and high CYP27A1-expressing	150
	groups according to the median expression of CYP27A1. Reported	151
	<i>P</i> values were calculated using the log-rank method.	152
	<i>CYP27A1 mRNA levels and promoter methylation.</i> Data from	153
	TCGA-PRAD, representing 246 patient samples, were used to	154
	correlate transcription start site (TSS) methylation levels with	155
	mRNA expression levels of CYP27A1. The intensity of the prox-	156
	imal TSS probe of CYP27A1 from the Infinium HumanMethyla-	157
	tion450 BeadChip was plotted against the Log ₂ mRNA CYP27A1	158
	expression levels from RNA-Seq. Data points were fitted with a	159
	loess smoothing curve.	160
	CYP27A1 IHC analysis	161
	The patient cohort and details of TMA construction were	162
	previously described (32). TMA sections were stained with anti-	163
	CYP27A1 rabbit monoclonal antibody (ab126785 from Abcam),	164
	and detailed protocol can be found in Supplementary Materials	165
	and Methods. Staining intensity in tumor cells was scored pro-	166
	spectively as 0 (absent), 0.5 (borderline), 1 (weak), 2 (moderate),	167
	or 3 (strong) by a board-certified pathologist (J. Geradts) blinded	168
	to clinical information. For statistical analysis, the tumors were	169
	categorized as negative (0 and 0.5) or positive (1, 2, and 3). A χ^2	170
	test was used to test association between expression of CYP27A1	171
	(treated as a binary variable) and PRAD versus benign tissue.	172
	Cell culture and <i>in vitro</i> assays	173
	<i>Cell lines and culture conditions.</i> LNCaP, 22RV1, DU145, and	174
	VCaP cells were obtained from the ATCC and were authenticated	175
	by the ATCC using short tandem repeat (STR) profiling. LAPC4	176
	cells were a generous gift from Dr. William Aronson (UCLA, CA)	177
	and authenticated by the ATCC using STR profiling. All cell lines	178
	were passaged in the laboratory for no more than 20 passages (or 4	179
	months). LNCaP and 22RV1 cells were cultured in RPMI-1640;	180
	DU145 in MEM; VCaP, 293FT, and 293Ts in DMEM; and LAPC-4	181
	in Iscove's DMEM supplemented with 0.1 nmol/L R1881. All	182
	media were also supplemented with 10% FBS, 1 mmol/L sodium	183
	pyruvate, and 0.1 mmol/L NEAA.	184
	<i>Gene silencing.</i> LNCaP cells were seeded at 3×10^5 cells per well on	185
	a 6-well plate and transfected with siRNA as indicated using	186
	Dharmafect I (Dharmacon) for 48 to 72 hours, unless otherwise	187
	specified.	188
	<i>Generation of stable cell lines.</i> pLenti CMV TRE3G puro Gal4-DBD	189
	and pLenti CMV TRE3G puro CYP27A1 were cotransfected	190
	(Fugene, Promega) with the vsvg, gag-pol, and rev packaging	191

194	vectors into 293FT cells. The viral supernatants were filtered and	
195	supplemented with 8 µg/mL polybrene before infecting LNCaP or	
196	22RV1 cells that constitutively express the pLenti CMV-rTA3G	
197	plasmid under blasticidin antibiotic selection. Cells were then	
198	selected with 1 µg/mL puromycin yielding Gal4- and CYP27A1-	
199	overexpressing cell lines.	
200	LDLR overexpression. pQCXIP or pQCXIP LDLR were cotrans-	
201	fected with the vsvg packaging vector into 293Ts cells. The viral	
202	supernatants were filtered and supplemented with 8 µg/mL poly-	
203	brene before infecting LNCaP cells. Forty-eight hours following	
204	infection, LNCaP cells were harvested and plated for proliferation	
205	assays.	
206	Western blotting, RNA preparation, qRT-PCR analyses, and	
207	proliferation assays were described previously (33–35).	
208	Anchorage-independent growth. Anchorage-independent growth	
209	was assessed by monitoring colony formation after 4 to 5 weeks in	
210	soft agar (0.6% base; 0.3% top layer) using 5,000 cells per well in	
211	6-well plates. Briefly, 0.6% agar (2 mL) in growth medium was	
212	added to a 6-well plate and allowed to solidify. Then, cells were	
213	suspended in 2 mL of 0.3% agar with or without 27HC (1 µmol/L)	
214	and were added on top of the agar base and allowed to solidify.	
215	Media containing DMSO or 27HC (1 µmol/L) were added to each	
216	well, and treatment was replaced every 3 days. Colonies were	
217	stained with crystal violet and counted using a phase contrast	
218	microscope.	
219	Apoptosis assay. LNCaP and 22RV1 cells (3×10^5 cells/well) were	
220	seeded in 6-well plates and treated accordingly. Cells were then	
221	harvested and double stained with Alexa Flour 488 Annexin V and	
222	Sytox according to the manufacturers' instructions. Annexin V-	
223	positive cells were considered apoptotic, and the percentage of	
224	total cell number was calculated. A minimum of 10,000 events	
225	were collected per sample using a BD Accuri C6 flow cytometer,	
226	and data were analyzed using the CFlow plus program software	
227	(BD Biosciences).	
228	Caspase 3/7 activity assay. The assay was performed as described in	
229	Fritz and colleagues (36) with modifications (see Supplementary	
230	Materials and Methods).	
231	27HC and cholesterol measurements. 27HC and cholesterol mea-	
232	surements were performed by the Duke Proteomics and Metabo-	
233	loomics Shared Resources. For details, see Supplementary Materials	
234	and Methods.	
235	Murine tumor xenograft model	
236	All xenograft procedures were approved by the Duke University	
237	Institute for Animal Care and Use Committee. Castrated Nod	
238	Scid/Gamma (NSG) mice (~6 weeks of age, $n = 20$ per group)	
239	obtained from the Cancer Center Isolation Facility (Duke Cancer	
240	Institute, Durham, NC) were subcutaneously injected with $1 \times$	
241	10^6 22RV1-Gal4 or 22RV1-CYP27A1 cells into the right flank in	
242	200 µL of a 50% mixture containing RPMI 1640 medium and	
243	Matrigel matrix basement membrane (BD Corporation). Doxy-	
244	cycline was added to the drinking water 2 days prior to xenograft	
245	injections. Tumors were measured by caliper 2 to 3 times/week for	
246	30 days after engraftment. At sacrifice, the tumors were harvested,	
247	weighed, and flash-frozen for subsequent analysis of RNA, pro-	
248	tein, and cholesterol.	
	Results	250
	Cholesterol availability influences the growth of prostate	251
	cancer cells <i>in vitro</i>	252
	As a first step in these studies, we assessed the impact of	253
	manipulating cholesterol levels on prostate cancer growth.	254
	More specifically, the consequence of altering media LDL levels	255
	(the lipoprotein with the highest cholesterol content) on the	256
	growth of prostate cancer cells was evaluated. To this end, VCaP	257
	cells were cultured in media with lipoprotein-deficient serum	258
	(LPDS), and their proliferation was assessed and compared	259
	with cells grown in full serum containing media. After 8 days,	260
	cell number, as measured by relative DNA content, increased	261
	1.3-fold in LPDS media versus a 3.4-fold increase in full serum	262
	media (Supplementary Fig. S1A). Adding LDL to LPDS media	263
	restored VCaP cell number to full serum media levels. Similar	264
	trends were observed in DU145 and 22RV1 prostate cancer	265
	cells, where LDL addition significantly enhanced growth when	266
	compared with cells grown in LPDS media (Supplementary Fig.	267
	S1B and S1C). These results established a relationship between	268
	cholesterol availability and prostate cancer cell growth rate and	269
	confirmed the importance of exogenous cholesterol for cancer	270
	cell growth.	271
	The expression of CYP27A1, a gene involved in cholesterol	272
	homeostasis, correlates strongly with prostate cancer	273
	clinical outcome	274
	Given our specific interest in developing therapeutics that	275
	target pathways involved in regulating cholesterol homeostasis,	276
	we used a bioinformatic approach to identify cholesterol-related	277
	genes whose expression correlated with aggressive prostate	278
	cancer in annotated clinical datasets. Specifically, a list of 176	279
	genes involved in cholesterol biology was derived using the	280
	following GO ontologies: "GO:0006695" = cholesterol bio-	281
	synthetic process, "GO:0042632" = cholesterol homeostasis,	282
	"GO:0045540" = regulation of cholesterol biosynthetic pro-	283
	cess, and "GO:0008203" = cholesterol metabolic process.	284
	Using data extracted from TCGA, the expression level of each	285
	of these genes relative to clinical features known to predict	286
	outcome such as T-stage, Gleason score at diagnosis, and the	287
	presence of lymph node metastasis was assessed. These genes	288
	were modeled for their association to these clinicopathologic	289
	features using logistic regression and evaluated using both the	290
	97.5% CI, OR, and statistical significance. To account for	291
	multiple testing, only genes with a P value less than 0.01 were	292
	considered significant. Though this does not fully account for	293
	multiple testing, we also did not want to miss important	294
	observations. Importantly, only one gene, CYP27A1, was sig-	295
	nificant for all three features with all three P values ≤ 0.001 , and	296
	ten genes (AKR1D1, APP, FXR, LIPE, STAR, APOF, LBR,	297
	MBTPS1, OSBPL1A, and SQLE) were significant for any two	298
	features. Applying this strategy, using P values as a primary	299
	selection criterion, low CYP27A1 expression was determined to	300
	be the most significant predictor ($P = 4.102E-08$) of high	301
	Gleason score, the second most significant predictor of lymph	302
	node involvement ($P = 8.220E-04$), and the sixth strongest	303
	significant predictor ($P = 1.460E-03$) of high T-stage (Table 1).	304
	To further dissect the relationship between low CYP27A1	305
	expression and high Gleason score, patients were divided into	306
	three groups; Gleason score <7 , $=7$, or >7 and the expression of	307
	CYP27A1 across the categories as reported in TCGA was	308

Q7

Table 1. *CYP27A1* expression is a strong predictor of adverse clinical features of prostate cancer

Gleason score

NOTE: Expression of genes involved in cholesterol regulation (derived from gene ontology analysis) was assessed for its ability to predict Gleason score at the time of diagnosis, lymph node involvement, and T-stage. All the data were extracted from TCGA, and calculations were done with R-software. Only the ten most highly ranked genes are shown for each clinical feature out of a total 176 genes shortlisted through GO analysis.

assessed (Fig. 1A). Notably, *CYP27A1* mRNA expression levels were significantly lower in patients with Gleason score >7 versus patients with Gleason = 7 ($P < 0.0001$) or Gleason < 7 ($P < 0.0001$).

Using data extracted from seven different GEO datasets, we looked for differences in *CYP27A1* expression between the different stages of clinical and pathologic disease progression (benign, primary, metastatic, hormone sensitive, and hormone refractory); *CYP27A1* transcript levels were significantly lower in tumor samples versus benign prostate tissue across all five datasets that included benign and prostate cancer tissue (Fig. 1B; Supplementary Table S1; and Supplementary Fig. S1D). Moreover, in three of the four datasets that included data on metastasis, *CYP27A1* expression levels were significantly decreased in metastatic tumors versus primary tumors (Supplementary Table S2 and Supplementary Fig. S1D). The effect of transitioning to castrate-resistant prostate cancer (CRPC; aka hormone-resistant prostate cancer or HRPC) on *CYP27A1* expression was not as clear as one dataset showed significantly lower expression in HRPC (Tamura-GSE6811), whereas in a second dataset (Tomlins-GSE6099), no significant difference in expression was noted (Supplementary Table S3 and Supplementary Fig. S1D). Querying the TCGA-PRAD dataset revealed a strong negative correlation between the *CYP27A1* mRNA

levels and DNA methylation at the TSS of this gene (Fig. 1C). This analysis suggests that an epigenetic event may be involved in the silencing of *CYP27A1* in prostate cancer.

To confirm that *CYP27A1* expression was also reduced at the protein level, we assessed *CYP27A1* protein using immunohistochemistry in tissue microarrays (TMA) that contained 1 mm cores from prostate cancer and benign prostate tissue. In these TMAs, the majority (89%; 106/119) of the benign cores expressed *CYP27A1*, whereas only 28% (28/101) of the cancer cores expressed *CYP27A1* (χ^2 , $P < 0.001$). A representative photomicrograph demonstrating the absence of *CYP27A1* staining in tumor cells (black arrows) and positive staining in benign cells admixed within the cancerous cells (red arrows) is shown in Fig. 1D.

To test whether *CYP27A1* expression can predict clinical outcome, we queried the Taylor-GSE21032 dataset and found that patients whose tumors exhibited higher *CYP27A1* expression also had a significantly reduced risk of PSA recurrence following radical prostatectomy (HR = 0.325, $P = 0.00211$; Fig. 1E). Taken together, these data establish a negative correlation between *CYP27A1* expression and prostate cancer progression.

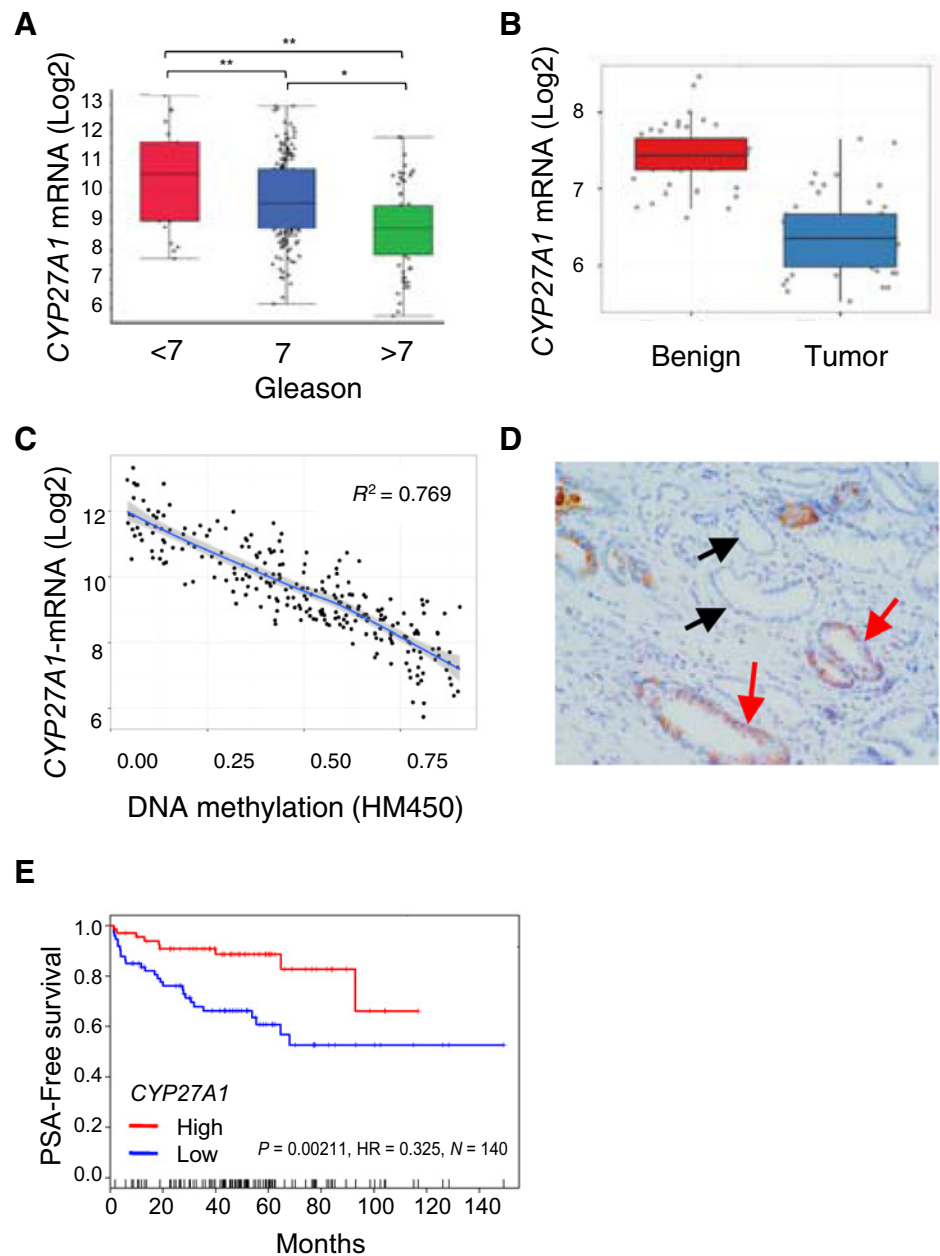

Restoration of *CYP27A1* expression slows the growth of prostate cancer cells *in vitro* and attenuates the growth of 22RV1 cell-derived xenografts

Next, we wanted to determine whether altering *CYP27A1* activity/levels affects prostate cancer cell growth. *CYP27A1* expression was first assessed in six prostate cancer cell lines (DU145, PC3, LNCaP, 22RV1, LAPC4, and VCaP) by immunoblot analysis. As shown in Supplementary Fig. S2A, only the androgen receptor (AR)-negative DU145 and PC3 cells express detectable levels of *CYP27A1* protein, although it is not known if this enzyme is active in these cells. As most prostate tumors express AR, even in late-stage CRPC (37), we elected to use the AR-expressing LNCaP and 22RV1 cells for further studies of *CYP27A1* biology. LNCaP and 22RV1 cells were engineered to stably overexpress *CYP27A1* or GAL4-DBD (control) both under the control of a doxycycline-inducible promoter. Doxycycline treatment resulted in a dose-dependent increase in *CYP27A1* mRNA and protein expression in LNCaP and 22RV1 cells with enforced *CYP27A1* expression but not in control cells (Supplementary Fig. S2B and S2C). Using the stably transfected cells described above, we assessed the effect of enforced *CYP27A1* overexpression on prostate cancer cell growth *in vitro*. It was observed that the growth of cells expressing *CYP27A1* was significantly impeded in both LNCaP and 22RV1 cells (Fig. 2A). Furthermore, these *CYP27A1*-expressing cells demonstrated significantly reduced ability to grow in an anchorage-independent manner (Fig. 2B).

22RV1 cells express a truncated, constitutively active, AR variant that confers resistance to all of the currently available androgen synthesis inhibitors and to antiandrogens and are a model of CRPC (38). Thus, considering the growth-inhibitory effects of *CYP27A1* overexpression on 22RV1 cells *in vitro*, the effect of *CYP27A1* overexpression on the growth of 22RV1 cell-derived tumors was evaluated *in vivo*. To this end, 22RV1 control cells (expressing GAL4) or those that overexpress *CYP27A1* were propagated as xenografts in castrated, immunodeficient mice, and tumor growth was assessed by caliper measurements. Two days prior to injection of tumor cells, mice were given doxycycline in their drinking water (Supplementary Fig. S2D). Starting at day

Figure 1.

CYP27A1 is lost in prostate cancer and predictive of progression. **A**, TCGA was queried for mRNA levels of *CYP27A1* in tumor samples, and Gleason score at the time of diagnosis. Patients whose tumors have a Gleason score >7 have significantly lower levels of expression of *CYP27A1* than patients whose tumors have a Gleason score = 7 or a Gleason score <7. *, $P < 0.05$; **, $P < 0.0001$. **B**, Data from Brase (GSE29079) was queried for mRNA levels of *CYP27A1*. *CYP27A1* transcript levels are significantly lower in tumor versus benign samples ($P = 2.84 \times 10^{-19}$). **C**, Data from TCGA-PRAD, representing 246 patient samples, were used to correlate TSS methylation levels with mRNA expression levels of *CYP27A1*. **D**, A representative photomicrograph of a cancerous prostate core immunostained for *CYP27A1* displays no staining for *CYP27A1* in the malignant epithelium (black arrows). Benign glandular epithelium admixed in the core displays moderate staining for *CYP27A1* (red arrows). **E**, The association of tumor levels of *CYP27A1* on patient survival was queried using the Taylor (GSE21032) clinical dataset. In this analysis, biochemical recurrence following radical prostatectomy was used as the primary end point. Kaplan-Meier curves generated for cancer patients with *CYP27A1* expression above or below the median indicate that patients whose tumors express higher levels of *CYP27A1* (above the median) have significantly delayed recurrence ($P = 0.00211$).

Q8

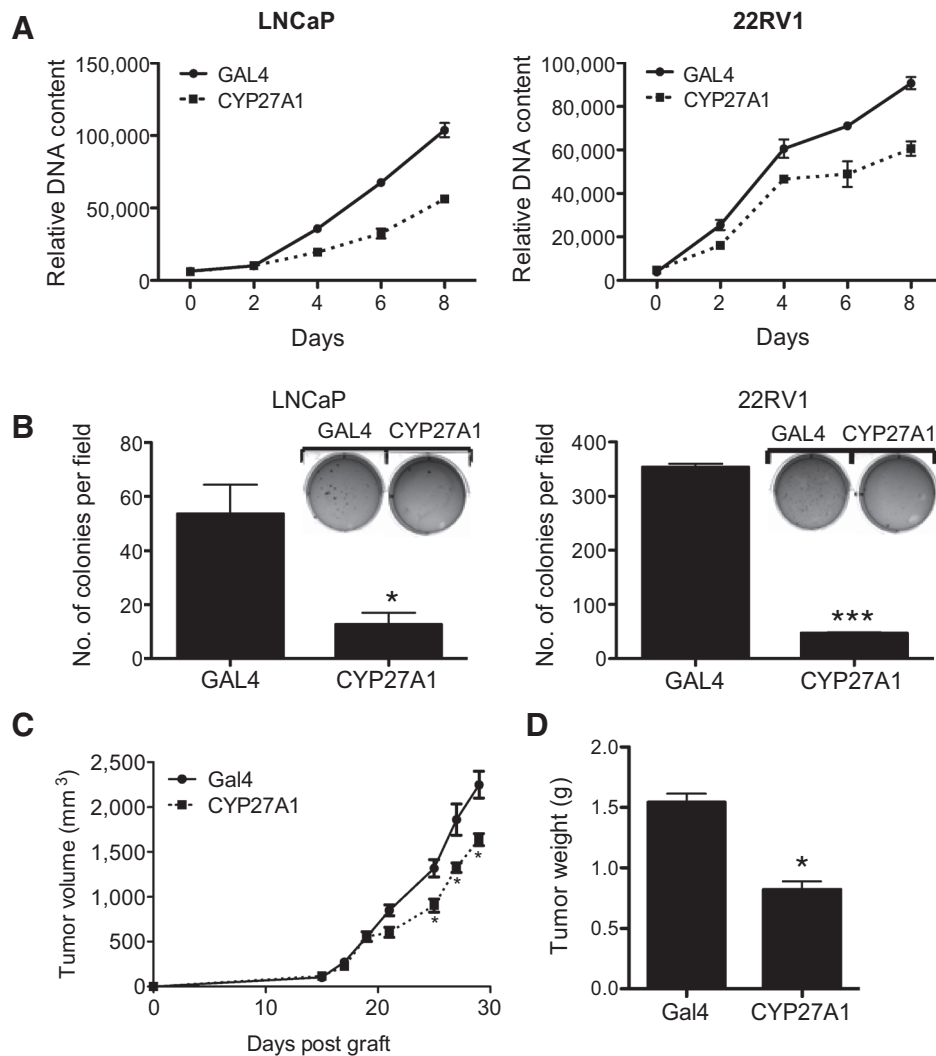

398 25 and continuing through the remainder of the study, tumors
399 expressing *CYP27A1* were significantly smaller than those expressing
400 *GAL4* (Fig. 2C). At sacrifice, the weight of tumors derived
401 from the *CYP27A1*-expressing cells was half that of tumors
402 expressing *GAL4* (Fig. 2D). Tumoral expression of *CYP27A1* was
403 confirmed by immunoblot analysis (Supplementary Fig. S2E). It
404 was concluded from these studies that restoring *CYP27A1* levels
405 negatively affects prostate cancer growth *in vitro* and *in vivo*.

406 **CYP27A1 inhibits the growth of prostate cancer cells via** 407 **production of 27HC**

408 The *CYP27A1* gene encodes a cytochrome P450 oxidase, sterol
409 27-hydroxylase, the primary activity of which is to convert cho-
410 lesterol into 27HC (30). In addition, however, it has been shown
411 that recombinant *CYP27A1* has weak vitamin D 25-hydroxylase

activity and, when assessed *in vitro*, can convert vitamin D₃ (calciferol) into 25-hydroxyvitamin D₃ (25(OH)D₃) (39). This is of potential significance as 25(OH)D₃ can be converted to 1,25-dihydroxyvitamin D₃ (1,25(OH)₂D₃) by *CYP27B1*, a seco-steroid that has been shown to inhibit the growth of many different cancer cells. Thus, to assess the extent to which the inhibitory effects of *CYP27A1* overexpression in PCa cells can be attributed to the production of 1,25(OH)₂D₃, we analyzed the expression of several genes which read on vitamin D receptor (VDR) activity in cells upon induction of *CYP27A1* expression (Supplementary Fig. S3). As expected, treatment with 1,25(OH)₂D₃ robustly induced the expression of several VDR target genes, such as *TMPRSS2* and *CYP24A1*, at concentrations as low as 1 nmol/L. However, overexpression of *CYP27A1* had no effect on the expression of these VDR targets ruling out the possibility that

Q9

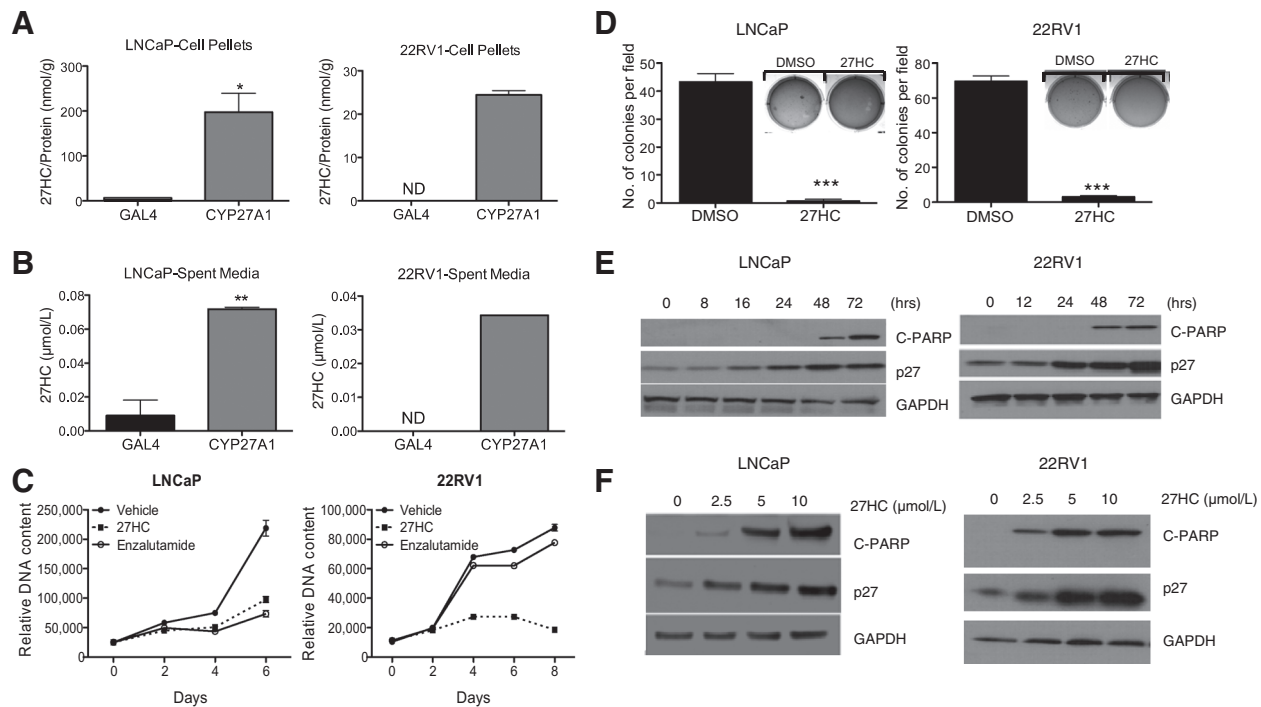

**Figure 2.**

27HC inhibits the growth of prostate cancer cells *in vitro* and in xenografts. **A**, LNCaP or 22RV1 cells stably expressing CYP27A1 or its GAL4 control were plated in full serum media. Twenty-four hours later, cells were treated with 25 ng/mL of doxycycline. Cells were then harvested at the indicated days and DNA content measured using Hoechst 33258. The data shown are a representative of three independent experiments. **B**, LNCaP or 22RV1 cells stably overexpressing CYP27A1 or GAL4 control were treated with doxycycline. Two days later, cells were seeded in soft agar in 6-well plates and incubated for 3 weeks. Colonies were stained with crystal violet. Graph represents the number of colonies growing in soft agar per microscopic field. Three different microscopic fields were counted per well. Experiments were done 3 times. Error bars represent the SEM; *, $P < 0.05$; **, $P < 0.001$ (unpaired *t* test). A representative well showing colonies growing in soft agar is also shown in the graph. **C**, Growth curve of GAL4- and CYP27A1-overexpressing tumors. 22RV1 cells (1×10^6) that stably expressed CYP27A1 or GAL4 (control) were implanted into the flanks of castrated NSG mice ($n = 20$ per group) and followed for tumor growth by calipers. Two days prior to tumor injection, mice were given doxycycline in the drinking water to induce CYP27A1 and GAL4 expression. Starting at day 25 after engraftment and continuing through the remainder of the study, tumors overexpressing CYP27A1 were significantly smaller than tumors overexpressing GAL4 (*, $P < 0.05$, Bonferroni T test following two-way ANOVA). **D**, Graph representing mean of the weights of GAL4- and CYP27A1-overexpressing tumors harvested at sacrifice (*, $P < 0.05$, *t* test).

430 functionally significant levels of $1,25(\text{OH})_2\text{D}_3$ were being produced upon reexpression of this enzyme. Notably, however, the expression of CYP27A1 resulted in increased production of intracellular 27HC in both LNCaP and 22RV1 cells when compared with control cells (Fig. 3A). A commensurate increase in 27HC in the spent media from CYP27A1-expressing cells was also observed (Fig. 3B). Because CYP27A1 overexpression inhibited prostate cancer cell growth, we next sought to determine if 27HC treatment results in a similar outcome. To this end, we compared the effects of 27HC on LNCaP and 22RV1 cell growth. Enzalutamide, an

antiandrogen used to treat advanced prostate cancer, was used as a control. 27HC inhibited the growth of both LNCaP and 22RV1 cells, whereas enzalutamide inhibited the growth of only LNCaP but not 22RV1 cells as expected, as these later cells express an AR splice variant(s) that confers resistance to antiandrogens (Fig. 3C; refs. 40, 41). An even more dramatic inhibitory effect of 27HC on anchorage-independent growth of prostate cancer was observed (Fig. 3D). Treatment of LNCaP and 22RV1 cells with 27HC was associated with a dramatic increase in cleaved PARP (marker of apoptosis), and p27 (marker of cell-cycle arrest) in a time- and

**Figure 3.**

27HC, produced by CYP27A1 in prostate cancer, slows the growth of prostate cancer cells *in vitro* and induces molecular markers of apoptosis and cell-cycle arrest. **A**, LNCaP and 22RV1 cells overexpressing CYP27A1 or its GAL4 control were plated and treated with doxycycline (25 ng/mL) for 7 days. 27HC levels were measured using a targeted LC-MS/MS method (see Materials and Methods) and normalized to total protein. Experiment was repeated 3 times, and error bars represent SEM (*, $P < 0.05$, unpaired t test). ND, not detectable (detection limit: 0.03 $\mu\text{mol/L}$). **B**, 27HC levels in spent media were measured as in **A** (*, $P < 0.05$, unpaired t test). **C**, Cells were seeded in 96-well plates for 24 hours and then treated with either 5 $\mu\text{mol/L}$ of 27HC, 5 $\mu\text{mol/L}$ of enzalutamide, or vehicle control (DMSO). Cells were harvested at the indicated days, and final DNA content was determined by staining with the DNA dye Hoechst 33258. The data shown are representative of three independent experiments. **D**, Cells were seeded in soft-agar plates and incubated for 3 weeks in the presence of vehicle (DMSO) or 1 $\mu\text{mol/L}$ 27HC. Colonies were stained with crystal violet. Graph represents the number of colonies per microscopic field. Three different microscopic fields were counted per well. Experiments were done 3 times. Error bars represent the SEM and ***, $P < 0.0001$ (unpaired t test). A representative well showing colonies growing in soft agar is also shown in the graph. **E**, Cells were plated in 6 cm dishes and treated with 10 $\mu\text{mol/L}$ 27HC the next day. Cell lysates were harvested at the indicated time points, and immunoblot analysis was performed to analyze expression levels of cleaved PARP (C-PARP) and p27. GAPDH was used as a loading control. **F**, Cells were treated with 27HC (2.5, 5, or 10 $\mu\text{mol/L}$) or vehicle control (DMSO) for 72 hours, and immunoblot analysis was performed as in **E**.

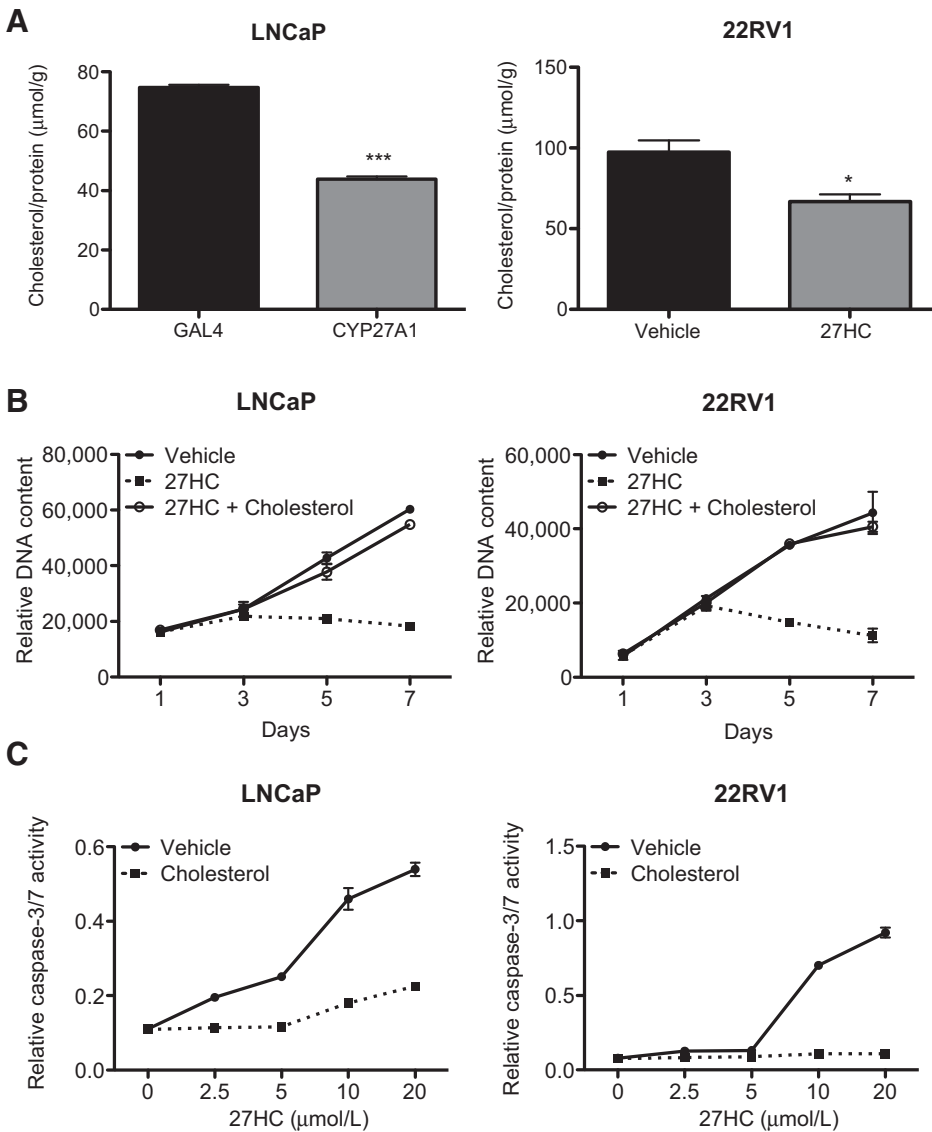

453 dose-dependent manner (Fig. 3E and F), and corresponding
 454 increases in apoptosis (Supplementary Fig. S5D). Analogous
 455 findings were observed when VCaP (AR amplified) and DU145
 456 (AR null) cells were treated in a similar manner (Supplementary
 457 Fig. S4A and S4D). It was noted, however, that 27HC treatment
 458 resulted in the induction of cleaved PARP in VCaP cells but not in
 459 DU145 cells (Supplementary Fig. S4B and S4C and data not shown).
 460 Conversely, 27HC treatment resulted in the induction of p27
 461 expression in DU145 but not in VCaP cells (Supplementary
 462 Fig. S4E and S4F and data not shown). The molecular basis for
 463 these differences is presently unclear, although all of the data are
 464 consistent with 27HC having a negative effect on prostate cancer
 465 viability irrespective of AR status.

27HC inhibits growth of prostate cancer cells via depletion of intracellular cholesterol

466 Some oxysterols, including 27HC, have been shown to partic-
 467 ipate in a negative feedback loop that is responsible for regulating
 468 cholesterol biosynthesis (31). To determine if the CYP27A1/27HC
 469 axis is involved in cholesterol homeostasis in prostate cancer cells,
 470 we first assessed the impact of 27HC administration on cholesterol
 471 levels in prostate cancer. As shown in Fig. 4A, treatment of prostate

475 cancer cells with 27HC resulted in a significant decline in cellular
 476 cholesterol in both LNCaP and 22RV1 cells by 35% ($P = 0.00152$)
 477 and 28% ($P = 0.00388$), respectively. Similar decreases in cellular
 478 cholesterol content were also observed in CYP27A1-overexpressing
 479 LNCaP cells but not in 22RV1 cells (Supplementary Fig. S5A).
 480 However, a significant decrease in total cholesterol was noted
 481 in CYP27A1-overexpressing 22RV1 tumors (Supplementary Fig.
 482 S5B). This latter discrepancy may relate to differences in the
 483 reliance on cholesterol synthesis versus uptake by these cells when
 484 propagated *in vitro* and *in vivo*.

485 A cholesterol complementation study was done to determine
 486 whether depletion of cholesterol is sufficient to explain the
 487 inhibitory effect of 27HC on prostate cancer growth. Indeed, the
 488 growth-inhibitory effects of 27HC on LNCaP and 22RV1 cells
 489 were reversed by adding exogenous cholesterol (Fig. 4B). Further,
 490 cholesterol supplementation reversed 27HC-dependent (a)
 491 induction of PARP cleavage (Supplementary Fig. S5C), (b)
 492 increases in the activity of effector caspases 3 and 7 (Fig. 4C),
 493 and (c) apoptosis (Supplementary Fig. S5D). Likewise, pretreating
 494 LNCaP or 22RV1 cells with LDL for 48 hours prior to the addition
 495 of 27HC significantly attenuated the antiproliferative effects of
 496 27HC (Supplementary Fig. S5E). These data are consistent with

**Figure 4.**

27HC inhibits growth of prostate cancer cells via depletion of cellular cholesterol. **A**, LNCaP or 22RV1 cells were treated with 10 $\mu\text{mol/L}$ of 27HC. Three days later, the cells were harvested, and cell lysates were extracted with RIPA buffer. Cellular levels of cholesterol were quantified using a targeted LC-MS/MS method (Materials and Methods). Experiment was repeated 3 times. Error bars represent the SEM and *, $P < 0.05$ was considered a significant variation (unpaired t test). **B**, LNCaP or 22RV1 cells were plated in 96-well plates. One day later, the cells were treated with 5 $\mu\text{mol/L}$ 27HC in the presence or absence of 10 $\mu\text{mol/L}$ cholesterol. Cells were harvested at the indicated days, and cell numbers were determined by staining with the DNA dye Hoechst 33258. The data shown are representative of three independent experiments. **C**, LNCaP or 22RV1 cells were plated in 96-well plates. One day later, the cells were treated with the indicated doses of 27HC in the presence or absence of 10 $\mu\text{mol/L}$ cholesterol. Caspase 3/7 activity was measured 48 hours later using a luminescent based assay. Caspase activity was normalized to DNA content of the cells stained with Hoechst 33258 measured from a parallel experiment. The data shown are representative of three independent experiments.

499 the idea that 27HC-mediated effects on cell growth are a result of
500 reduced cellular cholesterol content.

501 27HC-dependent inhibition of prostate cancer cell growth 502 occurs via downregulation/inhibition of SREBP2 activity

503 In light of the observation that direct addition of 27HC, or
504 overexpression of CYP27A1, reduced cellular cholesterol content and inhibited cell growth, it was of interest to define
505 the mechanisms by which 27HC affected cholesterol homeostasis. As mentioned above, the levels of cholesterol in cells
506 are regulated by uptake, efflux, and biosynthesis primarily through the coordinated activity of SREBPs and LXRs (24–26).
507 Therefore, the ability of 27HC to affect the expression of canonical LXR and SREBP target genes was assessed. Treatment of LNCaP and 22RV1 cells with 27HC resulted in the
508 upregulation of ABCG1 and a downregulation of LDLR mRNA expression (Fig. 5A and data not shown). The magnitude of
509 the induction of ABCG1 expression by 27HC is similar to that achieved with the synthetic LXR agonist T0901317 (T1317),
510
511
512
513
514
515
516

and depletion of LXR α and β isoforms by siRNA diminished this induction (Fig. 5A). This suggests upregulation of ABCG1
517 by 27HC is mediated by LXRs. On the other hand, downregulation of LDLR by 27HC was independent of the LXRs
518 as knockdown of LXRs did not rescue LDLR downregulation (Fig. 5A, right).
519
520
521
522
523

524 To determine the role of LXRs as a mediator of the growth-inhibitory effects of 27HC on prostate cancer cells, the ability of
525 the synthetic LXR agonist T1317 to phenocopy the effects of 27HC on *in vitro* growth of LNCaP and 22RV1 cells was assessed. Like
526 27HC, T1317 significantly inhibited the growth of LNCaP cells. However, 22RV1 cells which are 27HC responsive were not
527 inhibited by T1317 even at doses as high as 10 $\mu\text{mol/L}$ (Fig. 5B). Thus, although 27HC can function as an LXR agonist in
528 prostate cancer cells, its actions on overall cholesterol homeostasis and on cell proliferation are likely to occur, at least in part, in an
529 LXR-independent manner. Therefore, we assessed if SREBP2, which is also known to be involved in cholesterol homeostasis,
530
531
532
533
534
535
536

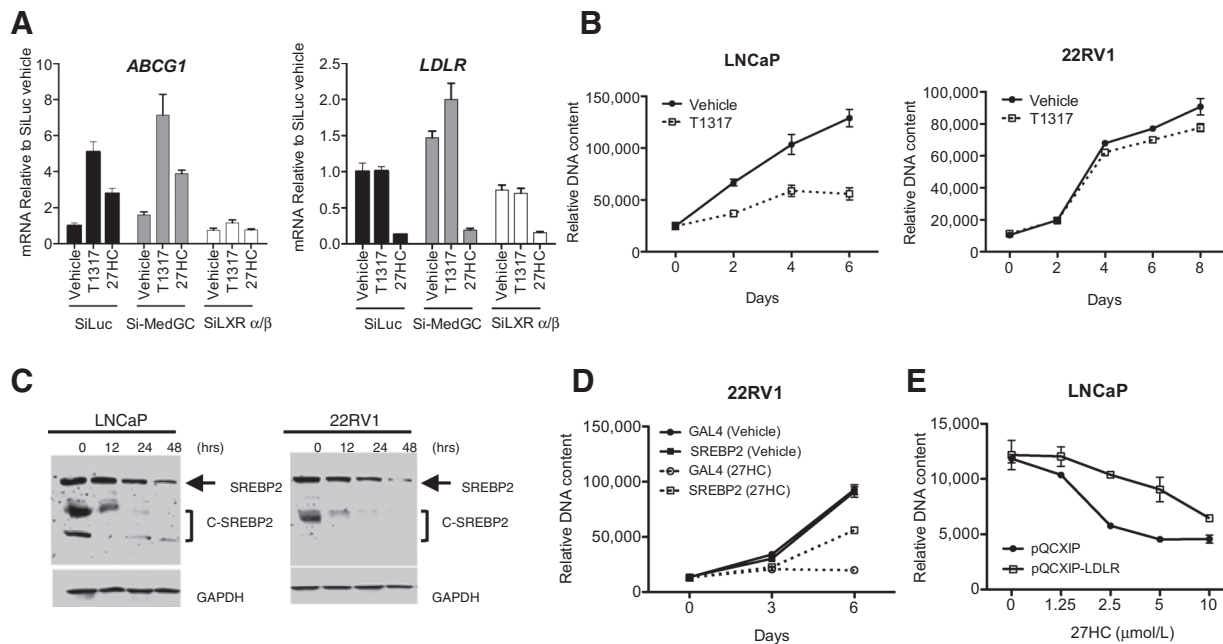

Figure 5.

27HC-dependent inhibition of prostate cancer cell growth occurs via downregulation/inhibition of SREBP2 activity. **A**, LNCaP cells were transiently transfected with siRNA targeting Si-Luc (negative control), or MED-GC (negative control), or LXRs (LXR- α and LXR- β). Two days later, the cells were treated with vehicle, or 27HC (10 $\mu\text{mol/L}$), or T1317 (10 $\mu\text{mol/L}$) for 18 hours. The expression of *ABCG1* and *LDLR* was assessed using qPCR. Data are presented as fold induction above vehicle-treated cells. The data shown are representative of three independent experiments. **B**, LNCaP or 22RV1 cells were plated in 96-well plates. The next day, cells were treated with T1317 (10 $\mu\text{mol/L}$) or vehicle control and harvested at the indicated time points. The DNA content of the cells was measured by Hoechst 33258. **C**, Cells were treated with 5 $\mu\text{mol/L}$ of 27HC and harvested at the indicated time points. Immunoblot analysis was performed to analyze expression levels of SREBP2, using an antibody specific to its C-terminus, and GAPDH (loading control). The arrow indicates precursor (full-length) form of SREBP2. Several smaller cleaved/processed forms of SREBP2 were also detected in the cell lysate (bracketed, C-SREBP2). **D**, 22RV1 cells that stably express active fragment of SREBP2 (N-terminus) or GAL4 control were plated in 96-well plates and treated with doxycycline (25 ng/mL) for 24 hours. The cells were then treated with 27HC (2.5 $\mu\text{mol/L}$) or its vehicle control and harvested on the indicated days following treatment. Final DNA content of the cells was determined as in **B**. The data shown are representative of three independent experiments. **E**, LNCaP cells were transiently infected with a retrovirus that carries LDLR (PQCXIP-LDLR) or an empty vector as a negative control (PQCXIP-CTRL). Forty-eight hours later, cells were harvested and a proliferation assay was performed in the presence of the indicated doses of 27HC. Seven days later, cell numbers were determined by staining with the DNA dye Hoechst 33258. The data shown are representative of three independent experiments.

539 in Fig. 5C, treatment with 27HC led to a time-dependent decrease
 540 in the levels of the precursor form of SREBP2 in LNCaP and 22RV1
 541 cells, consistent with the downregulation of SREBP2 mRNA
 542 expression by 27HC (data not shown). This is likely due to the
 543 fact that SREBP2 activity is required for its own transcription (42).
 544 We next tested whether the effects of 27HC on cell growth can be
 545 reversed by exogenously expressing the active nuclear form of
 546 SREBP2 (43, 44). For this purpose, 22RV1 cells engineered to
 547 stably overexpress the active form of SREBP2 or GAL4 (control)
 548 under the control of a doxycycline-inducible promoter were
 549 developed. Overexpression of SREBP2 significantly reduced the
 550 sensitivity of 22RV1 cells to 27HC (Fig. 5D). Because LDLR is a
 551 major downstream target of SREBP2, we evaluated whether LDLR
 552 overexpression alone could abrogate 27HC-mediated antiprolif-
 553 erative effects. Indeed, LNCaP cells that were transiently infected
 554 with an LDLR-expressing retrovirus were found to have an atten-
 555 uated response to 27HC (Fig. 5E). Finally, we demonstrated that
 556 siRNA-mediated knockdown of LDLR expression phenocopied
 557 the effects of 27HC on prostate cancer growth (Supplementary
 558 Fig. S6A–S6C). It was concluded from these studies that 27HC-
 559 dependent downregulation of SREBP2 activity and LDLR expres-
 560 sion in part explains the antiproliferative effects of 27HC on
 561 prostate cancer.

Discussion

The results of this study provide a potential mechanistic link
 between dysregulated cholesterol homeostasis and prostate cancer
 pathogenesis and highlight approaches that can be used to
 mitigate the impact of dyslipidemia on the biology of this disease.
 Notable was our observation that the expression of CYP27A1, a
 key component of the cellular cholesterol homeostatic machin-
 ery, was dramatically downregulated in advanced prostate cancer,
 an activity that may result from hypermethylation of the gene
 encoding this protein. Absent this enzyme, an important negative
 feedback mechanism that regulates cellular cholesterol homeo-
 stasis is lost leading to cholesterol accumulation, which endows a
 selective growth advantage upon prostate cancer cells (Supple-
 mentary Fig. S6D). Whereas the mechanisms by which increased
 cholesterol synthesis/uptake affects prostate cancer cell growth
 remain under investigation, it is clear from our studies that
 restoration of the activity of the CYP27A1/27HC signaling axis
 and/or modalities that decrease cellular cholesterol content are
 likely to have a positive impact on prostate cancer treatment/
 prevention.

In addition to the data presented here, other preclinical studies
 have shown that intratumoral cholesterol homeostasis and

negative feedback loops are deregulated in prostate cancer (45–47). For example, *LDLR* mRNA and *SREBP2* expressions are downregulated in the presence of exogenous LDL or cholesterol in normal prostate cells but not in the prostate cancer cells (45). Although both normal and prostate cancer cells respond to low cholesterol media by upregulating cholesterol uptake and/or synthesis genes, prostate cancer cells have considerably lower expression of the cholesterol exporter *ABCA1*, thus potentially allowing them to accumulate more cholesterol (47). This supports the idea that prostate cancer cells have reprogrammed cholesterol homeostatic gene networks, which may enable them to become resistant to cholesterol-lowering drugs. Although this has not been tested directly in prostate cancers from patients on cholesterol-lowering drugs, a recent window of opportunity trial in breast cancer patients which showed that administration of atorvastatin, while lowering circulating cholesterol as expected, actually resulted in an upregulation of the expression of intratumoral *HMGCR*, the rate-limiting enzyme in cholesterol biosynthesis (48). This important clinical finding suggests that when faced with reduced availability of LDL-cholesterol, cancer cells can respond by increasing intracellular cholesterol production, a finding that questions whether lowering circulating cholesterol in and of itself would have a significant impact on the intracellular levels of cholesterol within cancer cells and thereby slow prostate cancer growth. It is intriguing to speculate that this fact explains why the epidemiologic data linking cholesterol and statin use and prostate cancer are mixed, with many studies suggesting no such link (49). Ultimately, future studies wherein both serum and intratumoral cholesterol are measured are required to test the true link between cholesterol and prostate cancer.

The findings of this study suggest that, as with other rapidly dividing cells, prostate cancer cells must have developed mechanisms to bypass the processes that regulate intracellular cholesterol content to enable them to accumulate cholesterol that has been shown to constitute an important checkpoint in cell division (50). We believe, given what is known about the role of oxysterols in the negative feedback control of cholesterol biosynthesis/uptake, that prostate cancer cells accomplish this activity by blocking the synthesis of 27HC as a consequence of *CYP27A1* gene silencing. In support of this hypothesis, we have shown that ectopic expression of *CYP27A1* in prostate cancer cells decreases cellular and intratumoral cholesterol accumulation and inhibits cell/tumor growth. Mechanistically, we have shown that 27HC mediates this effect in part through downregulation of *SREBP2*, which in turn suppresses *de novo* synthesis and uptake of cholesterol. In support of this model, we have shown that the growth-inhibitory activity of 27HC is considerably attenuated by ectopic expression of activated *SREBP2* or by overexpression of *LDLR* from a heterologous promoter. Thus, it appears that downregulating *CYP27A1* expression in prostate cancer cells interferes with an important negative feedback mechanism that enables these cells to accumulate the cholesterol needed for cell growth.

In addition to functioning as a partial agonist of LXRs and an inhibitor of *SREBP2* activity, 27HC has also been shown to interact with estrogen receptors α and β (ERs; ref. 51). Both of these ERs have been reported to be expressed in prostate tissue, although their exact roles in prostate cancer development and progression remain unresolved (52). It has been shown that activation of ER β is protective against prostate cancer (52, 53), a finding that may be significant given that 27HC has been shown to inhibit the transcriptional activity of both ER isoforms in the cardiovascular system but demonstrated partial agonist activity in the breast tissues. However, despite considerable effort, we were unable to detect significant expression of either ERs in any of the prostate cancer cell models used in our study (data not shown). This argues for the noted antiproliferative and proapoptotic effects of 27HC in prostate cancer are ER-independent. Notably, however, a recent article described an ER- and AR-dependent growth-promoting effect of 27HC in nontransformed RWPE-1 prostate epithelial cells (54). It remains to be determined whether this effect is due to the agonist activity of 27HC on ER in these cells, similar to what has been observed in breast cancer cells (34), or that 27HC has opposite effects in transformed versus non-transformed prostate epithelial cells.

In summary, like most rapidly dividing cells, prostate cancer cells need to bypass the tight homeostatic mechanisms that regulate the levels of intracellular cholesterol. The data presented in this study indicate that this can be accomplished in prostate cancer cells by downregulating the expression of *CYP27A1*, thus inhibiting the production of 27HC, a molecule involved in feedback control of cholesterol synthesis and uptake. It remains to be determined how this regulatory activity can be restored and/or how the effects of the increased cholesterol uptake that result from the loss of *CYP27A1* expression can be mitigated. It is unlikely that statin use alone would have a significant effect, as it has been shown in other cancers that such an approach may lead to an upregulation of cholesterol biosynthesis in tumors (48). It would appear that the therapeutic options to target this pathway in cancer are limited to (1) the induction of the expression of genes involved in cholesterol efflux (such as LXR agonists), (2) approaches that reverse the inhibition of *CYP27A1* expression/activity and (3) *SREBP2* inhibitors or other compounds which interfere with cholesterol biosynthesis. It has been shown that LXR agonists can inhibit the growth of prostate cancer in animal models (55), the growth, and metastasis of melanoma (56), and we have also shown that they can decrease the growth of mammary tumors (34). Inhibitors of *SREBP1/2* and oxidosqualene cyclase have also shown promise in preclinical models of prostate cancer (57, 58). Exploration of the viability of these approaches, especially in combination, as a means to mitigate cholesterol-enhanced cancer risk, is a focus of our continued research.

Development of methodology: M.A. Alfaqih, E.R. Nelson, W. Liu, J. Geradts, J.W. Thompson, M.R. Freeman, S.J. Freedland
Acquisition of data (provided animals, acquired and managed patients, provided facilities, etc.): M.A. Alfaqih, E.R. Nelson, W. Liu, R. Safi, E. Macias, J. Geradts, J.W. Thompson, L.G. Dubois, C.-y. Chang, S.J. Freedland
Analysis and interpretation of data (e.g., statistical analysis, biostatistics, computational analysis): M.A. Alfaqih, E.R. Nelson, W. Liu, R. Safi, J.S. Jasper, E. Macias, J. Geradts, L.G. Dubois, M.R. Freeman, C.-y. Chang, D.P. McDonnell, S.J. Freedland
Writing, review, and/or revision of the manuscript: M.A. Alfaqih, E.R. Nelson, W. Liu, R. Safi, J.S. Jasper, E. Macias, J. Geradts, J.W. Thompson, L.G. Dubois, M.R. Freeman, C.-y. Chang, J.-T. Chi, D.P. McDonnell, S.J. Freedland
Administrative, technical, or material support (i.e., reporting or organizing data, constructing databases): J.-T. Chi, D.P. McDonnell, S.J. Freedland
Study supervision: E. Macias, J.-T. Chi, D.P. McDonnell, S.J. Freedland

711 **Acknowledgments**

712 The authors would like to thank Dr. Wes Pike (University of Wisconsin,
713 Madison) for advice on the design of experiments to explore potential roles of
714 CYP27A1 on vitamin D biology in prostate cancer cells.

715 **Grant Support**

716 This work was supported by R01DK048807 (D.P. McDonnell),
717 R00CA172357 (E.R. Nelson), 3R01-CA125618-08S1 and The Stewart Rahr
718 Prostate Cancer Foundation Young Investigator Award (E. Macias), CA131235

and 5K24CA160653-03 (S.J. Freedland), and DOD W81XWH-12-1-0102 (M.A.
Alfaqih). M.A. Alfaqih was a postdoctoral scholar of King Hussein Institute for
Biotechnology and Cancer (KHIBC, Amman, Jordan).

The costs of publication of this article were defrayed in part by the payment of
page charges. This article must therefore be hereby marked *advertisement* in
accordance with 18 U.S.C. Section 1734 solely to indicate this fact.

Received October 10, 2016; revised January 10, 2017; accepted January 10,
2017; published OnlineFirst xx xx, xxxx.

AUTHOR QUERIES

AUTHOR PLEASE ANSWER ALL QUERIES

- Q1: Page: 1: AU: Per journal style, genes, alleles, loci, and oncogenes are italicized; proteins are roman. Please check throughout to see that the words are styled correctly. AACR journals have developed explicit instructions about reporting results from experiments involving the use of animal models as well as the use of approved gene and protein nomenclature at their first mention in the manuscript. Please review the instructions at <http://www.aacrjournals.org/site/InstrAuthors/ifora.xhtml#genomen> to ensure that your article is in compliance. If your article is not in compliance, please make the appropriate changes in your proof.
- Q2: Page: 1: Author: Please verify the drug names and their dosages used in the article.
- Q3: Page: 1: Author: Please verify the affiliations and their corresponding author links.
- Q4: Page: 1: Author: Please verify the corresponding author details.
- Q5: Page: 1: Author: Note that AACR journals do not use such abbreviations as "BC" for "breast cancer," "CRC" for colorectal cancer, or "Pca" for "prostate cancer," or other *ad hoc* two-word abbreviations for diseases that incorporate a part of the body. However, these abbreviations are acceptable in tables or figures where space is an issue as long as they are defined in the legend or table notes.
- Q6: Page: 2: Author: Units of measurement have been changed here and elsewhere in the text from "M" to "mol/L," and related units, such as "mmol/L" and "μmol/L," in figures, legends, and tables in accordance with journal style, derived from the Council of Science Editors Manual for Authors, Editors, and Publishers and the *Système international d'unités*. Please note if these changes are not acceptable or appropriate in this instance.
- Q7: Page: 4: Author: Please verify the layout of Table 1 for correctness.
- Q8: Page: 5: Author: Please confirm quality/labeling of all images included within this article. Thank you.
- Q9: Page: 5: Author: Please define "PCa."
- Q10: Page: 10: AU:/PE: The conflict-of-interest disclosure statement that appears in the proof incorporates the information from forms completed and signed off on by each individual author. No factual changes can be made to disclosure information at the proof stage. However, typographical errors or misspelling of author names should be noted on the proof and will be corrected before publication. Please note if any such errors need to be corrected. Is the disclosure statement correct?
- Q11: Page: 10: Author: The contribution(s) of each author are listed in the proof under the heading "Authors' Contributions." These contributions are derived from forms completed and signed off on by each individual author. As the corresponding author, you are permitted to make changes to your own contributions. However, because all authors submit their contributions individually, you are not permitted to make changes in the

contributions listed for any other authors. If you feel strongly that an error is being made, then you may ask the author or authors in question to contact us about making the changes. Please note, however, that the manuscript would be held from further processing until this issue is resolved.

Q12: Page: 11: Author: Please verify the headings "Acknowledgments" and "Grant Support" and their content for correctness.

Q13: Page: 11: Author: Please provide journal name, volume, and page range for ref. 36.

AU: Below is a summary of the name segmentation for the authors according to our records. The First Name and the Surname data will be provided to PubMed when the article is indexed for searching. Please check each name carefully and verify that the First Name and Surname are correct. If a name is not segmented correctly, please write the correct First Name and Surname on this page and return it with your proofs. If no changes are made to this list, we will assume that the names are segmented correctly, and the names will be indexed as is by PubMed and other indexing services.
